

Chapter recap

Last updated December 2025

Nice work! You're slowly but surely learning JavaScript.

Have you noticed that we're using semi-colons in our code?

Semi-colons are optional in JavaScript. You can decide whether to include them or not.

The reason why they exist is that the JavaScript code you write will be minified once you deploy your website to production. This will be covered in more detail in a later chapter!

Challenges and projects will get more interesting as we learn more about JavaScript.

Next up, variables!

Chapter Recap

- Convert from a number to a string: `value.toString()`
- NaN stands for Not a Number
- NaN is often a sign of a bug.
- Convert from string to number `Number.parseInt(value, 10)`.
- `Number.parseInt()` is the name of the function you're calling.
- 10 is the **radix** which you should specify.
- Make sure to always specify the radix to avoid unpleasant surprises.
- The remainder operator (%) returns the division remainder between 2 numbers.
- `Math.round()` rounds a number to the nearest whole number; if the decimal part is 0.5 or higher, it rounds up, otherwise it rounds down.
- `Math.floor()` always "floors" (rounds down) the number to the next lower integer.
- `Math.ceil()` always "ceils" (rounds up) the number to the next higher integer.
