

Chapter recap

Last updated January 2022

Defining variables will allow us to work on more interesting challenges, especially after we learn about arrays (covered in chapter 6).

Variables defined with `let` and `const` are "block scoped". This will be explained the first time we encounter a block inside a function.

If you're coming from the learnprogramming.online you may have noticed that we did not mention `const` at all in that course. That was on purpose to make your life slightly easier while you were learning programming. Now that you know about `const`, try to use it when possible though as you can see, everything also works with `let`. It's just that `const` will give you a guarantee that when you define something as an array (for example) it will stay an array.

Recap

- When you use a variable for the first time in JavaScript, you need to declare it with either `let` or `const`.
- Use `let` for variables that you will need to re-assign later on (as in changing their value)
- Use `const` for variables that you won't need to re-assign later on.
- Variables declared with `const` are **not** constant. We will see why later in this course.
- Variables declared with `const` cannot be re-assigned so you cannot have the `=` next to that variable name after declaring it.
- If you see `var`, it's from the old version of JavaScript. You can convert it to `let` (sometimes `const` if the variable is not re-assigned).
